Diabetic Nephropathy: Strategy for Therapy (Developments in Nephrology)

Diabetic Nephropathy: Strategy for Therapy (Developments in Nephrology)

Diabetic nephropathy is a tragic illness. Its often insidious onset in the insulin dependent (type I) diabetic, typically a young adult, heralds the last act in the course of a disease that will increasingly become the dominant preoccupation in the patient's shortened life. For most type II diabetics, the beginning of clinical renal insufficiency is but a phase in a continuous deterioration that affects the integrity of job, marriage, and family. The nephropathic diabetic is hypertensive, has worsening retinopathy, and more often than not, is also plagued by peripheral vascular insufficiency, heart disease, gastrointestinal malfunction, and deepening depression. Until the 1980's, few type I diabetics who became uremic (because of diabetic nephropathy) lived for more than two years. Hardly any attained true rehabilitation. This dismal prognosis is changing substantially for the better. Research in diabetes has resulted in striking advances at both ends of the type I diabetic's natural history. In one exciting clinical trial now underway in London, Ontario, half of childhood diabetics treated with cyclosporine within six weeks of onset evince "permanent" disappearance of hyperglycemia and the need for insulin. At the other end of the natural history of diabetes for the nephropathic patient with worsening eye disease (renal-retinal syndrome), who receives a kidney transplant, patient and graft survival, two years after cadaveric kidney transplantation in type I diabetics is now equal to that of the nondiabetic.
